What is the reason for there to be two different functions to get the name of the month? def get_name(year, month): "monthname(year, month) -> the name of the month" # Note: `1` not `0`! if month == 1: return "January" elif month in [2, 3, 4, 5, 6, 7, 8, 9]: return "February" + " " + get_name(year, 2) elif month in [10, 11, 12]: return "December" else: raise ValueError("Unknown month") def get_name(year, month): "monthname(year, month) -> the name of the month" month = month % 12 + 1 if month in [1, 3, 5, 7, 8, 10, 12]: return "January" + " " + get_name(year, month-1) elif month in [4, 6, 9]: return "April" + " " + get_name(year, month-4) elif month in [2, 10, 11]: return "July" + " " + get_name(year, month-7) else: raise ValueError("Unknown month") A: Both look to be the same, the only difference being that the second one assumes the current month is always the first of a particular month. This is because most people would expect that if you add X months to the current month you add X weeks to the date corresponding to that month. The month_name function names

Abby Flexicapture 9 0 keygen torrent. Flexicapture 9 0 Crack - Serial Number is a world-renowned. Abby Flexicapture Pro 9.The present invention relates to molding plastic containers, and more particularly to a molding machine for the injection molding of thermoplastic plastic containers of the type used in the wine and beverage industry, and similar applications. The present invention is directed to improvements in the injection molding of a thermoplastic material into a mold cavity in a mold. In such a molding operation, a mold cavity is defined by a pair of mold sections. Each of the mold sections has an internally threaded female mold half and an external male mold half. One of the mold halves carries a movable insert or core member while the other mold half carries a complementary male mold half. A plastified resin material in an injection molding operation is forced into the mold cavity by a core element (usually an element mounted on the insert) and solidified to form the completed plastic container. The plastic material is forced into the mold cavity by an injection unit, which includes a source of pressurized resin, a ram, and a nozzle which directs the resin toward the mold cavity. The mold sections are mounted to form a mold cavity through which the injected resin flows before it is solidified in the cavity. The nozzle of the injection unit can be mounted on a slide-type mount. In the normal molding operation, the mold sections, the nozzle mount, and the injector nozzle constitute the injection unit. By sliding the injection unit between the open mold sections, the injection unit can be placed between mold sections to define a mold cavity in which the nozzle of the injection unit is inserted to direct the injected resin into the cavity. Such mold arrangements can have a number of disadvantages. For instance, the nozzle mount can be driven by a shaft which extends through a wall of the mold cavity to engage and drive the nozzle mount. This means that the extended nozzle mount projects into the mold cavity which produces a large amount of liquid resin in the mold cavity between the extended nozzle mount and the mold half at all times. This liquid resin not only creates a messy and unprofessional environment, but it also acts as a heat sink, and thus retards the injection molding process. While the above described problem is present with mold arrangements of the slide-type, it also presents a particular problem when the
